2022 - 2023 (odd)

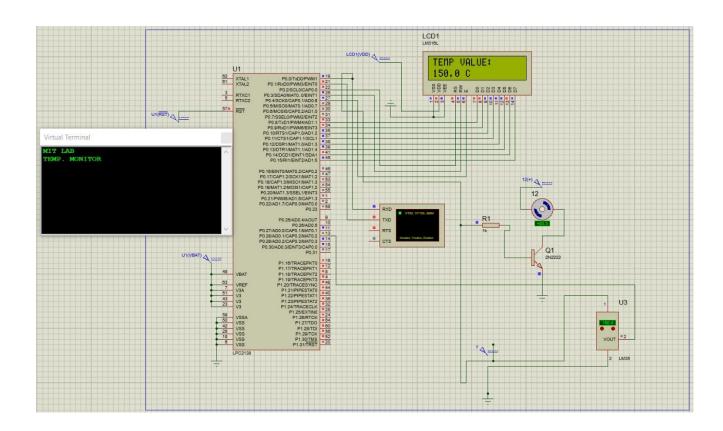

## **MOTIVATION:**

The motivation for this project is to create a system that automatically controls the temperature of an air conditioner. This can be useful in various settings, such as homes and offices, where maintaining a comfortable temperature is important. The apparatus used to control temperature in such environments are manual in nature. A person should constantly monitor the system and manually turn on or turnoff the device. Also, there may be considerable wastage of power in manual operation of these devices. Therefore, an automatic air conditioning system is required to perform the function of both the cooling devices and heating devices.

## THEORY:

We can construct automatic air conditioning system in a variety of way. We may use microprocessor/microcontroller based system or other custom designed circuits for the task. The LPC2138 microcontroller is used in this project to control the air conditioner. The microcontroller receives input from a temperature sensor, which is used to measure the current room temperature. The microcontroller then compares this temperature to a desired temperature set by the user. If the current temperature is higher than the desired temperature, the microcontroller will activate the air conditioner to cool the room. If the current temperature is lower than the desired temperature, the microcontroller will turn off the air conditioner, or increase the temperature. Basically, it consists of microcontroller as a central processor of the entire control operation. The temperature sensor gives the analog output voltage based on the temperature of the room. This analog voltage is fed to the A/D converter. The A/D converter then converts the analog input voltage from the temperature sensor into equivalent binary bits. The converted binary data from the A/D converter is applied to microcontroller. The microcontroller reads binary data from A/D converter, converts it to suitable form and performs different operations based on the value of temperature read from A/D converter.

# **DESIGN**:

# CODE:

void UART0\_Init(void);

```
#include <LPC213X.H>
/***********************************/
#define LCD_CLEAR
                             0x01

```

## **RESULTS:**

The system was tested by setting the desired temperature to different values and observing the behavior of the air conditioner. The system was able to accurately control the temperature of the room and maintain it at the desired level.

Following are the general results of this project:

- i. Temperature of the room is measured.
- ii. The temperature is displayed in LCD.
- iii. Temperature of the room is monitored and maintained according to the necessity.

## **INFERENCES:**

This project has presented a means of controlling temperature of a room and maintain it within a limit. This system can be useful in various settings for maintaining a comfortable temperature and saving energy by only using the air conditioner when necessary. It is also very marketable because of its simplicity, low cost, low power consumption and small size. It can be used in various other industrial applications such as to control the temperature in boilers, refrigerators, computers and Laboratories. The automatic temperature control system using the LPC2138 microcontroller was able to successfully control the air conditioner and maintain the temperature of the room at the desired level in this project.
